INTRODUCTION

If the device does not start and the Sensor Lens is in good condition, then the Circuit Board may be faulty and need replacement.

## 🔧 TOOLS:

- Tamper Resistant TORX Plus TR Bit (1)
- Phillips #1 Screwdriver (1)
- Phillips #2 Screwdriver (1)
- iFixit Opening Tools (1)

Step 1 — Server Board

- Begin by removing both screws and the brushed metal casing. Simply lift up at the indicated area with your hand.

- ⓘ The INSTALL and REMOVE indicators may be incorrect, so exercise caution when removing the screws.

Step 2

- Remove both 3/8" Ph2 screws attached to the grey belt at the top and bottom.

- Lift the grey belt away. This gives access to the server board.

Step 3

- Remove all three 1/2" Ph1 screws connecting the server board to the device.

- ⭐ During reassembly, install the screws before reattaching the wires.

Step 4

- Use a plastic opening tool to remove the two pink capped wires in the upper left corner of the server board.

- Use the same tool to dislodge the white capped ribbon bus with the multi-colored wires.

- After these steps, the server board should easily come off the side of the device.

To reassemble your device, follow these instructions in reverse order.
